- State of the art detection probes
- $^1\text{H}$ ,  $^2\text{H}$ ,  $^{13}\text{C}$ ,  $^{15}\text{N}$ ,  $^{19}\text{F}$  &  $^{31}\text{P}$  NMR
- Solution & Solid State NMR applications

# Neutron diffraction beamlines

## LADI-III: quasi-Laue neutron diffractometer

- Data collection at RT or cryogenic temperatures using Cobra cryostream; e.g. cryo-trapping studies of enzymatic reaction intermediates
- Optimized for high- to medium-resolution (1.5 – 2.5Å) studies of large (50 – 120Å on edge) unit-cell systems using perdeuterated crystals (0.05mm<sup>3</sup> – 0.5mm<sup>3</sup>)

## D19: thermal neutron monochromatic diffractometer

- Monochromatic data collection ( $\lambda_{\text{mono}}$  0.8 – 2.4Å, e.g.  $\lambda = 1.46\text{\AA}$ )
- Large (120° x 30°) PSD 'banana' detector
- Optimized for high-resolution (better than 1Å) studies of smaller (30 – 70Å on edge) unit-cell systems using crystals > 1mm<sup>3</sup>

# SANS/SAXS platform

**D22: small-angle neutron scattering diffractometer**

**BM29: BioSAXS**

**New mode of operation in 2016 for integrated access**

# How to access PSB platforms?

- Peer Review

next deadlines

ESRF: 1<sup>st</sup> March 2016

ILL: 9<sup>th</sup> February 2016

- Transnational access (INSTRUCT, i-NEXT, BIO-NMR,...)

- Proprietary/paid-for access mode

## SCIENTIFIC HIGHLIGHTS

### Large Scale Conformational Dynamics Control the Function of H5N1 Influenza Polymerase

The structure of the PB2-NLS domain (green and red) of the PB2 domain of H5N1 viral polymerase opens and closes at a rate of around 300s<sup>-1</sup> at room temperature. Both forms can be studied simultaneously by NMR spectroscopy (top right). The open form interacts with Importin  $\alpha$  (yellow) allowing transport of this part of the polymerase into the nucleus of the cell. These results were derived from a combination of NMR (top right and left), single-molecule FRET (bottom left), and small angle X-ray and neutron scattering (bottom). © Martin Blackledge

A unique combination of complementary physical techniques has been used to reveal the molecular function of a protein essential for replication of H5N1 influenza virus [1]. A sub-domain of the viral polymerase undergoes large-scale structural reorganization to enable an essential part of the polymerase to enter the nucleus of the infected cell, where the viral genome is replicated. This study published in the *Journal of the American Chemical Society*, illustrates how the flexibility of a protein allows it to adapt its function, facilitating infection of the host.

The polymerase allows the virus to reproduce: copies of its genomic material in the infected cell, and thereby produce new viruses. It is known that adaptation of the influenza virus occurs through mutations in the viral polymerase, in particular in the C-terminal domain PB2-NLS of the PB2 polymerase protein. This two-domain protein is required for import of the viral polymerase into the nucleus, by binding to importin  $\alpha$ .

The protein has been crystallized, in isolation [2] and in the context of the entire polymerase [3], but the crystallized conformation appeared incapable of binding to importin  $\alpha$ , due to a strong steric clash between importin  $\alpha$  and PB2-NLS. The molecular basis of this essential interaction therefore remained mysterious [4].

Combining nuclear magnetic resonance spectroscopy (NMR), small

angle scattering (SAS) and single molecule Förster resonance energy transfer (sm-FRET), researchers at the IBS, UVHCI, EMBL and ILL revealed that in solution the protein exhibits a far more complex behavior. In fact the crystalline conformation indeed exists in solution, but this conformation exchanges, around 100 times per second, with another form of the protein, in which the two domains, attached by a flexible linker, dissociate and can move quite freely relative to each other.

Crucially, the 'open' form of the protein indeed interacts with importin  $\alpha$  - via a highly dynamic interaction - and it is this conformational equilibrium that allows for PB2 to enter the nucleus. NMR exchange spectroscopy shows that the rate of exchange between 'open' and 'closed' forms of the protein, and their populations, are highly temperature dependent, and it seems possible that this thermodynamic equilibrium between closed and open conformations plays a role as a molecular thermostat, controlling the efficiency of viral replication in the different species where the virus needs to evolve as a function of the temperature of the host environment.

This study again highlights the remarkable efficiency of viruses to exploit conformational flexibility to extend their functional diversity with limited genetic material. The same two-domain protein has at least two distinct functions: the 'closed' form is necessary for viral replication within the polymerase once the protein enters the nucleus, but the 'open' form is necessary for import into the nucleus.

More generally, inter-domain dynamics play crucial roles in a multitude of molecular recognition, transport and signaling processes. These complex dynamic modes cannot be understood from static structures of either the entire protein or individual domains. The study demonstrates the importance of solution-state structural biology to accurately describe the relationship between structure, dynamics, thermodynamics and biological function.
